

qwen3.5-9b: which phases dominate latency across context lengths?

Perf-pass wall intervals; 256 output tokens. Every context has a DFlash row and its own native AR row. Total = median TTFT + median decode; stage medians are closed with a remainder. Tiny phases remain in the CSV. Remainder includes crops, synchronization and bookkeeping: their individual wall times were not recorded. Hybrid results use stock rollback. 64K† range limits apply as in the original figures.
