

D4 verification overhead: absolute cost, output-token cost and latency share

Verify interval / token cost Native AR token step Entire DFlash decode / token Verify share of E2E

Left compares one block verification to one AR token step; block includes anchor plus up to 15 proposals.
Middle divides all verify interval time by 255 decode output tokens, so it includes acceptance and step counts.
Right separates decode share from entire-request share (TTFT + decode). Every number comes from perf-pass timers.
Hybrid speedups and acceptance use stock rollback; exact-state restoration cost has not been measured here.
